## Let's revisit Experimental Design!

Kanan Saikai

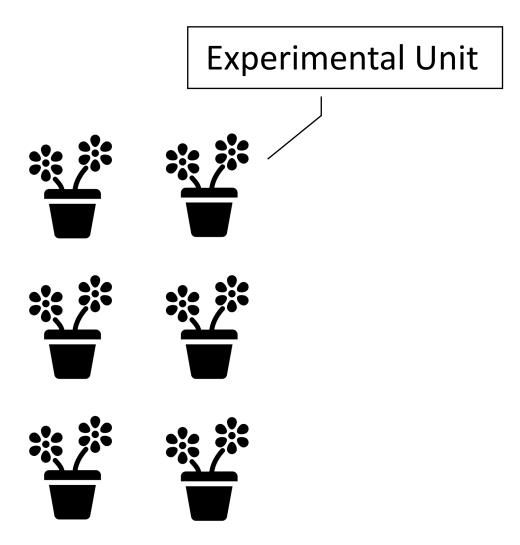

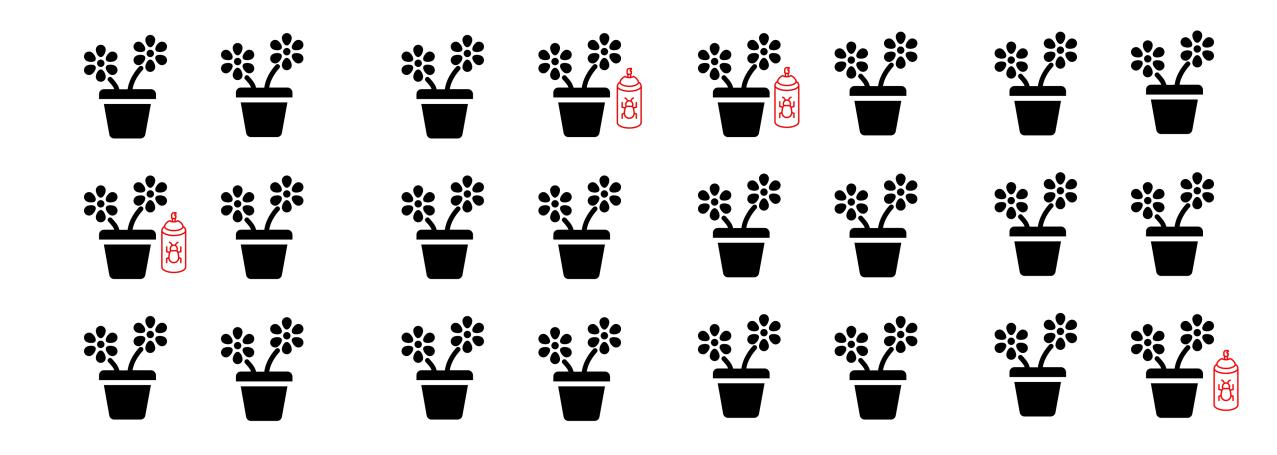

#### "Randomization"

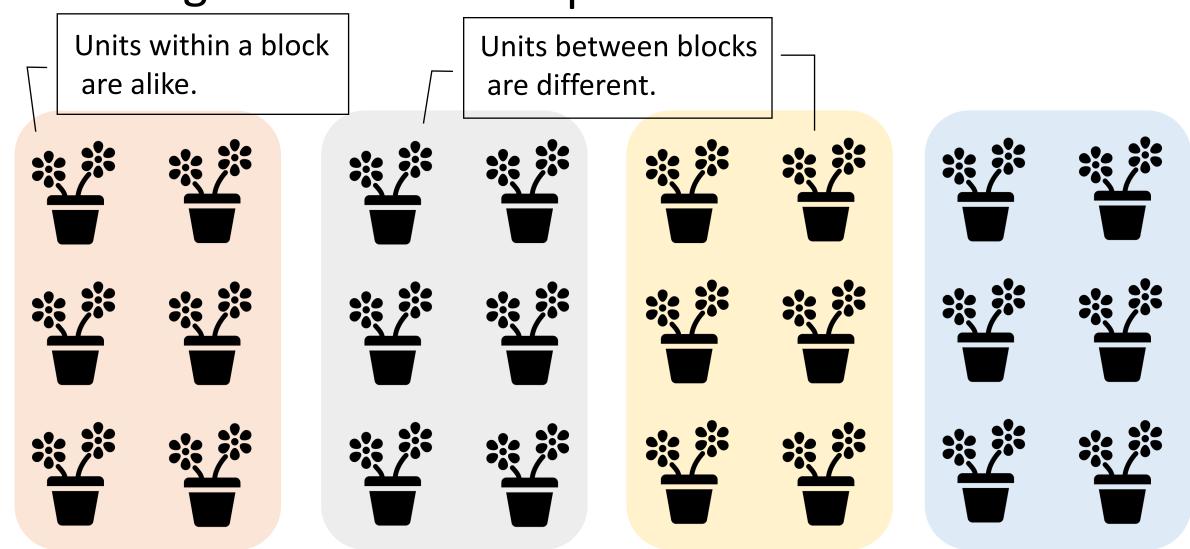

6 treatment

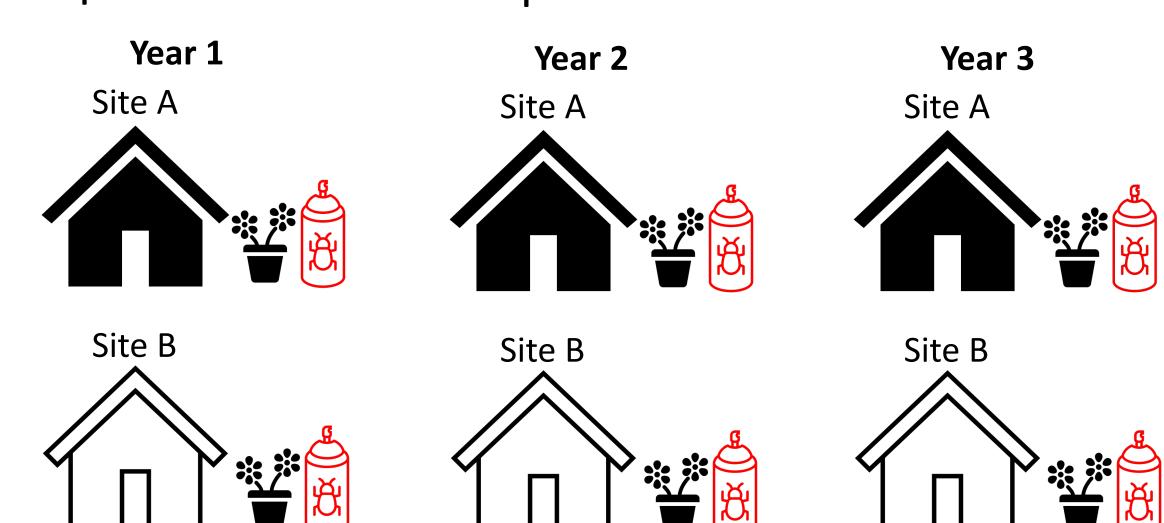

"Replication" to obtain an estimate of error variation

"Blocking" = reduces unexpected error

"Repetition" = increase precision and confidence.

#### What is Complete Randomized Design (CRD)

#### Treatments = 6

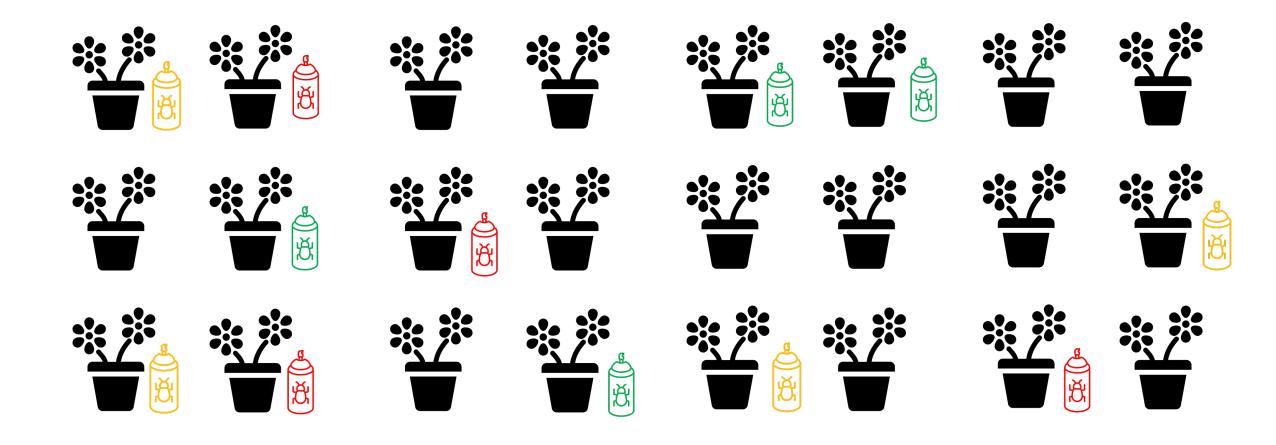

4 replications

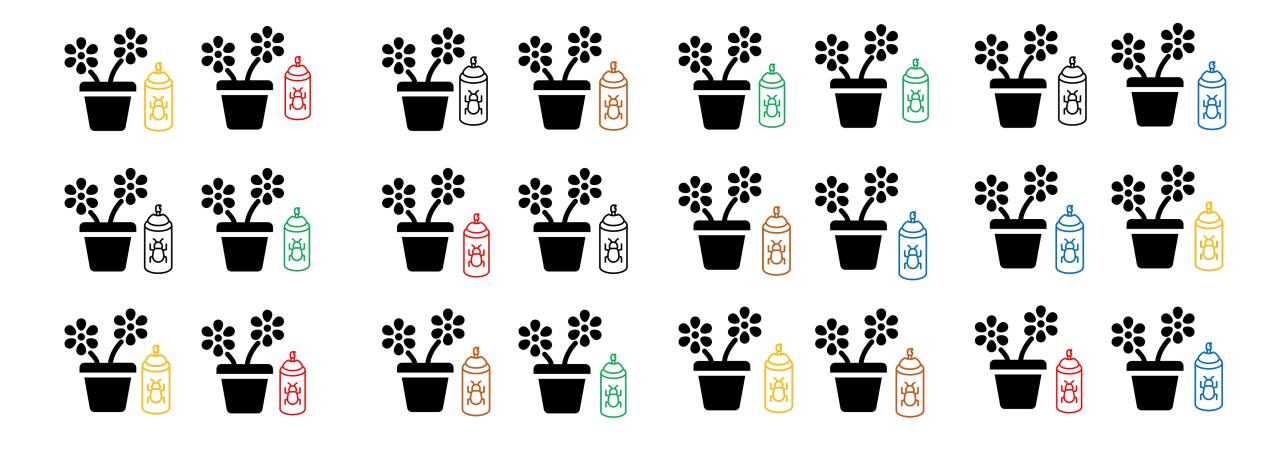

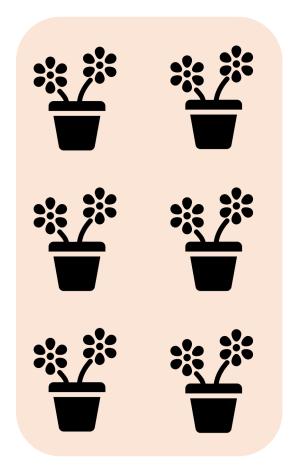

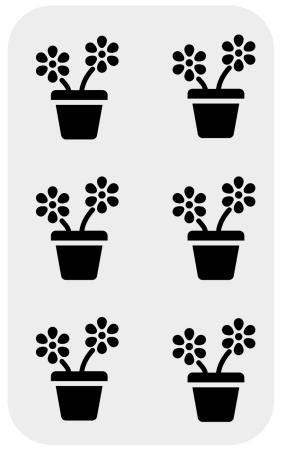

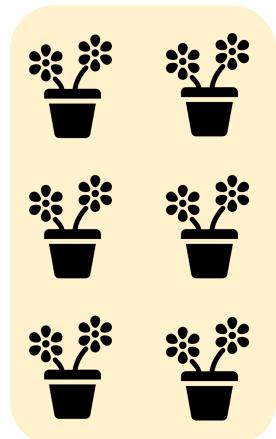

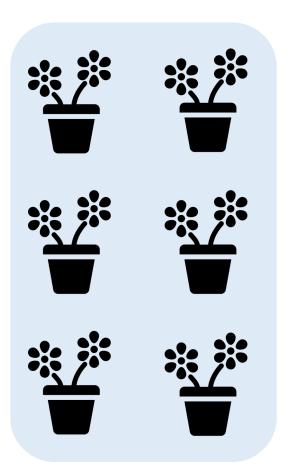

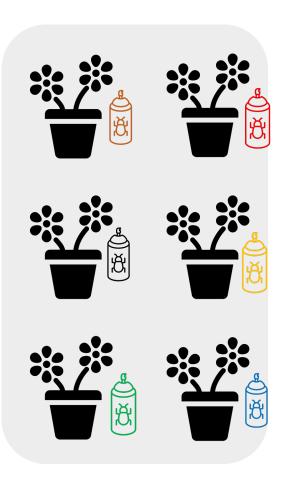

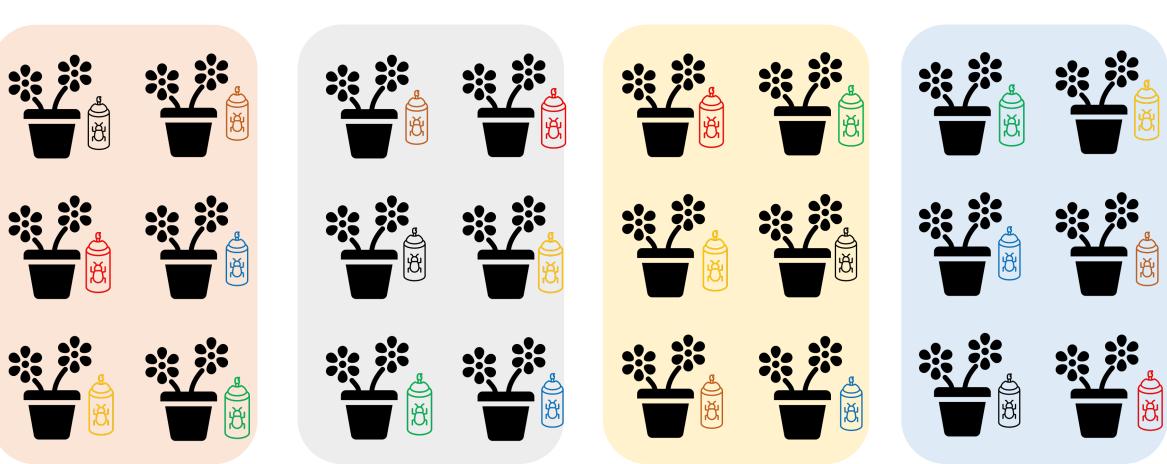

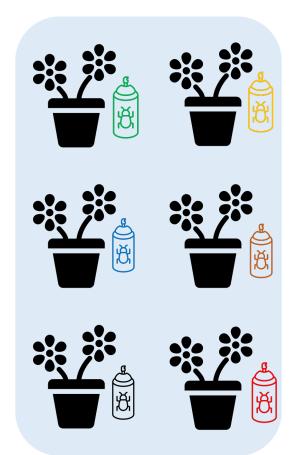

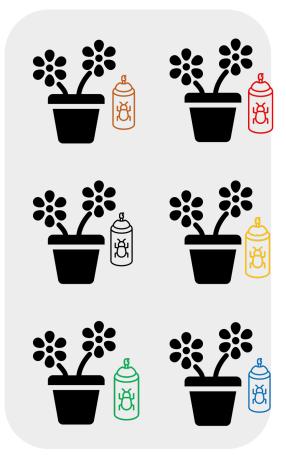

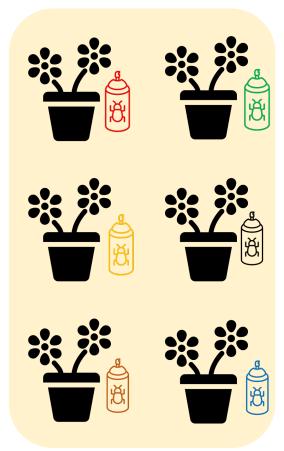

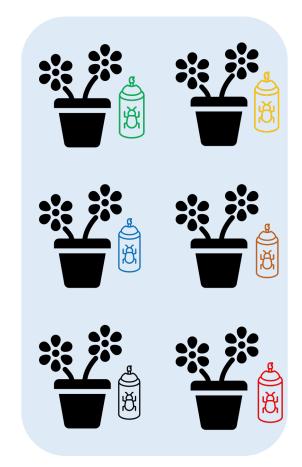

Units within a block are alike.

Units between blocks are different.

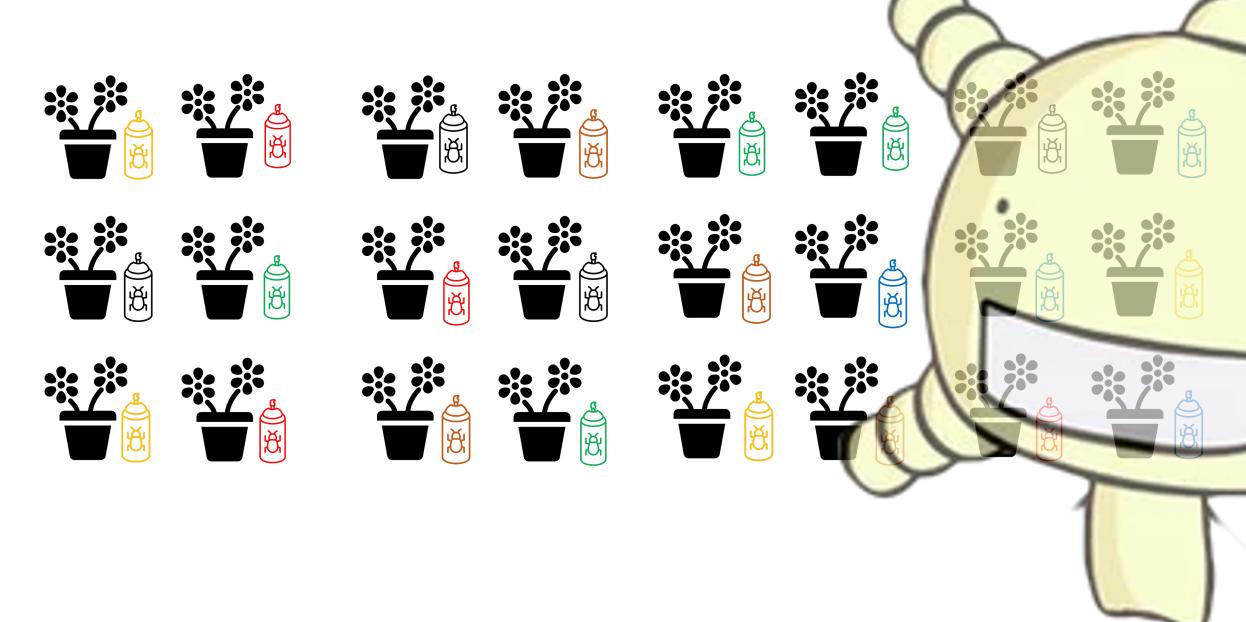

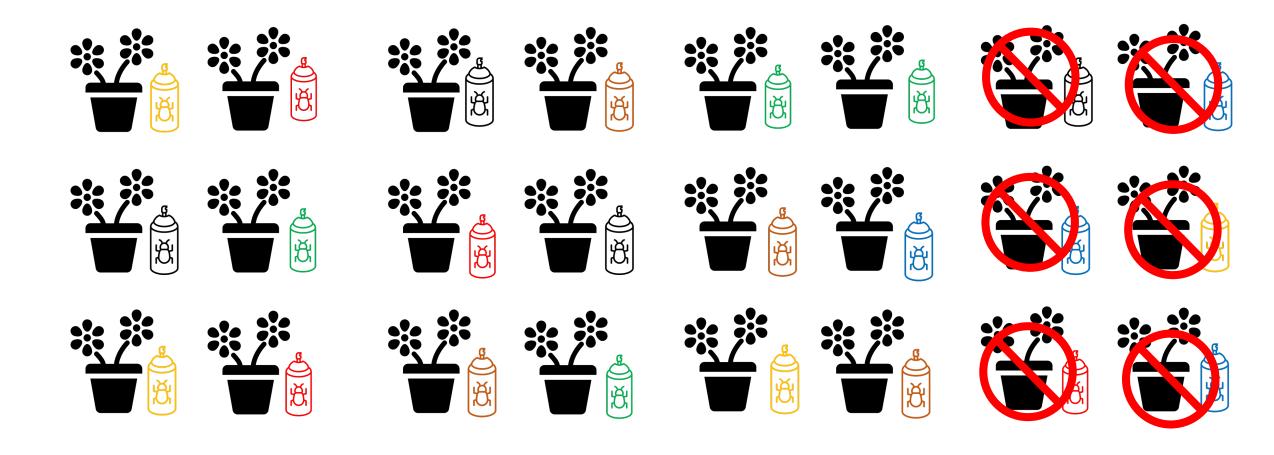

All treatments appear once in a block

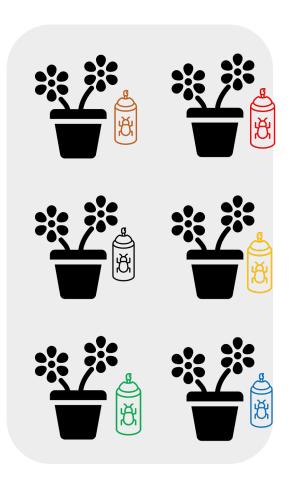

## So why RCBD over CRD?

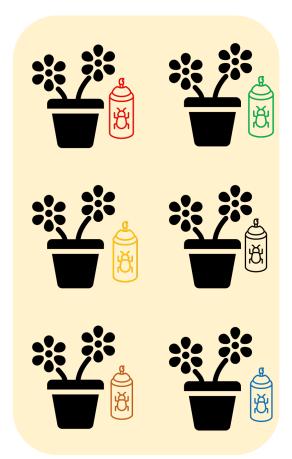

#### **Door**

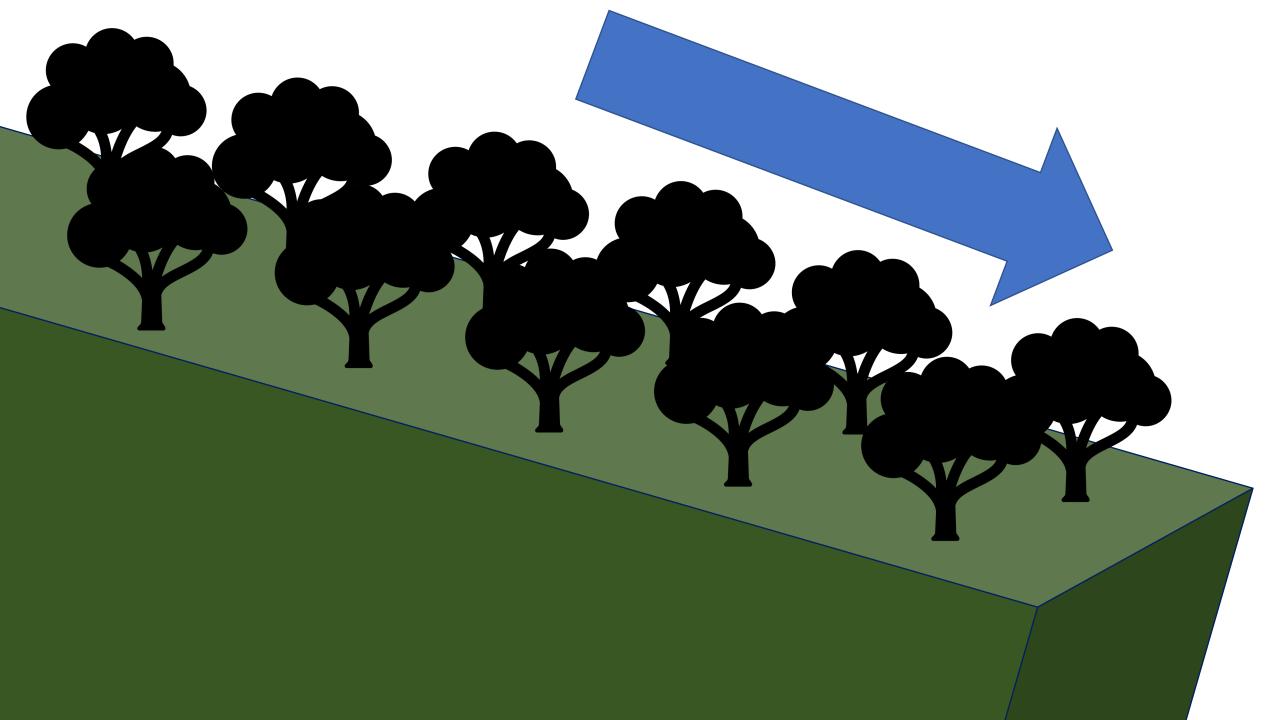

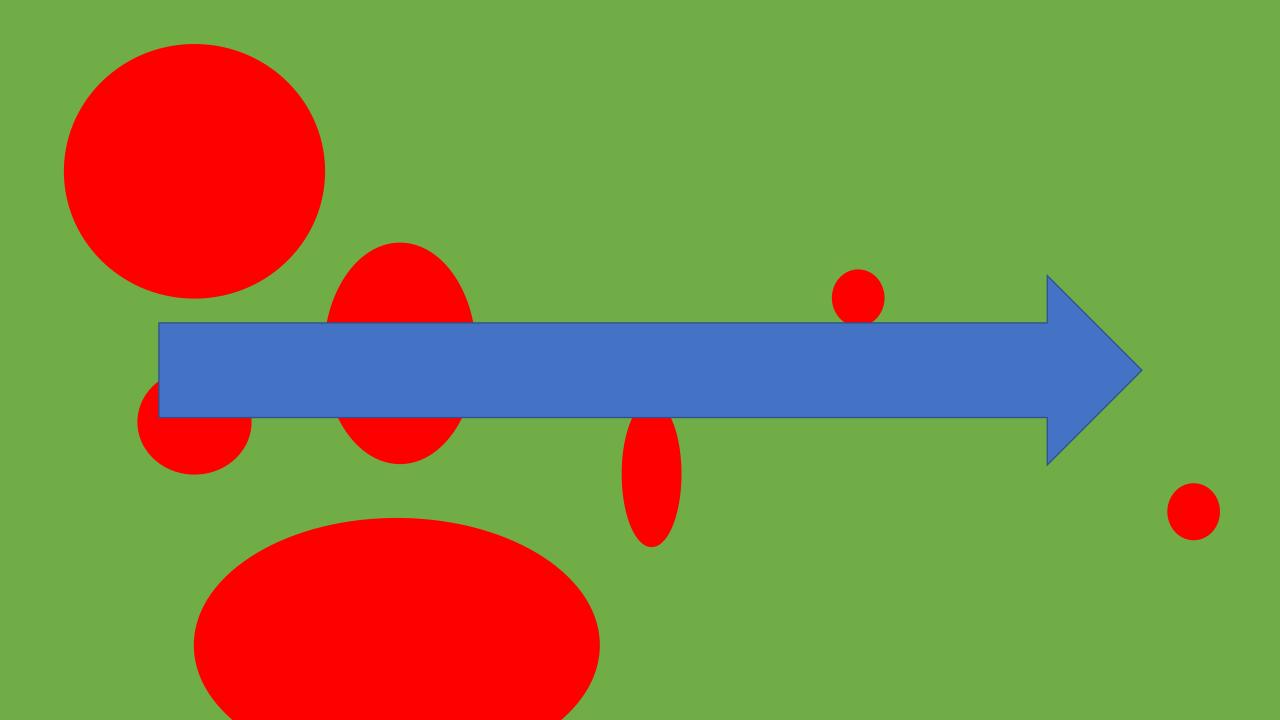

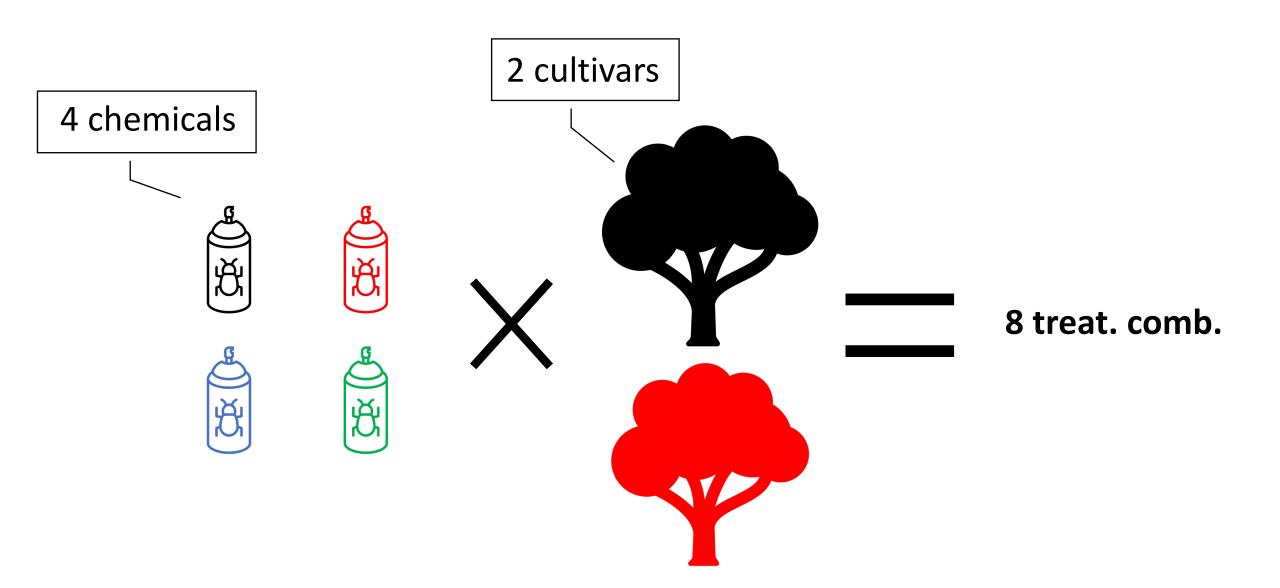

Fan

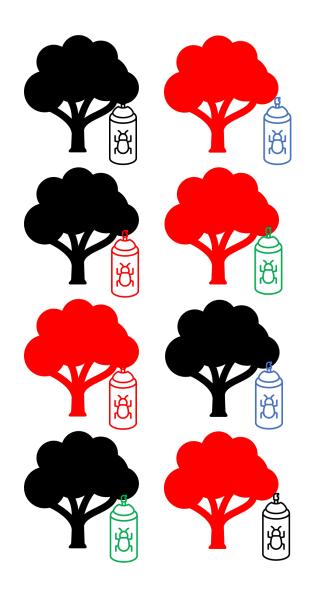

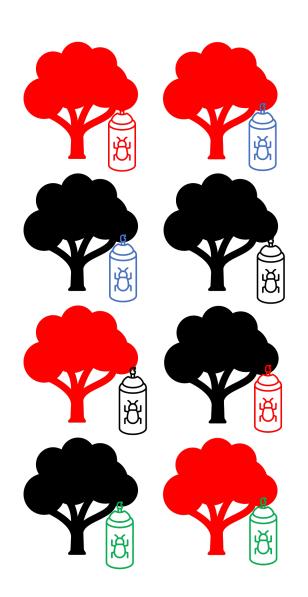

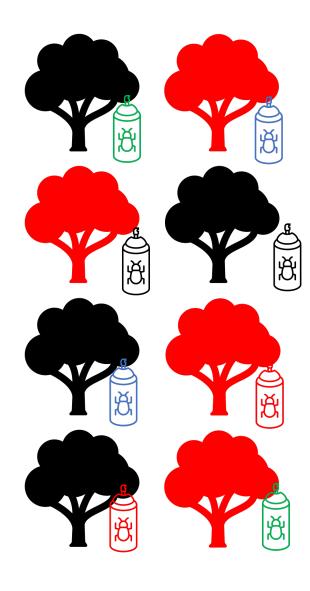

### What is **Split-plot Design**

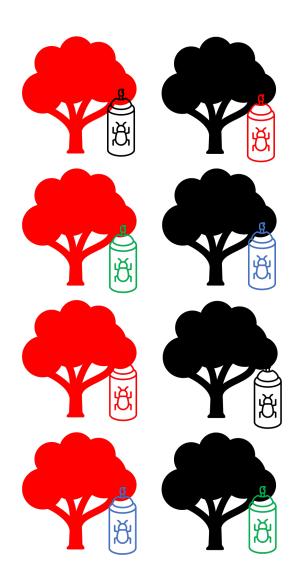

### Idealy...

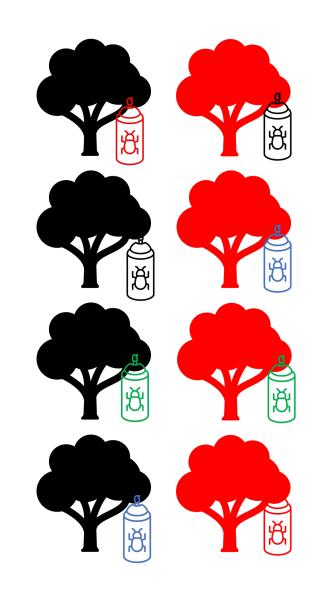

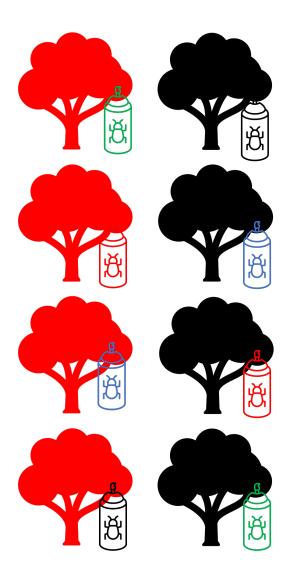

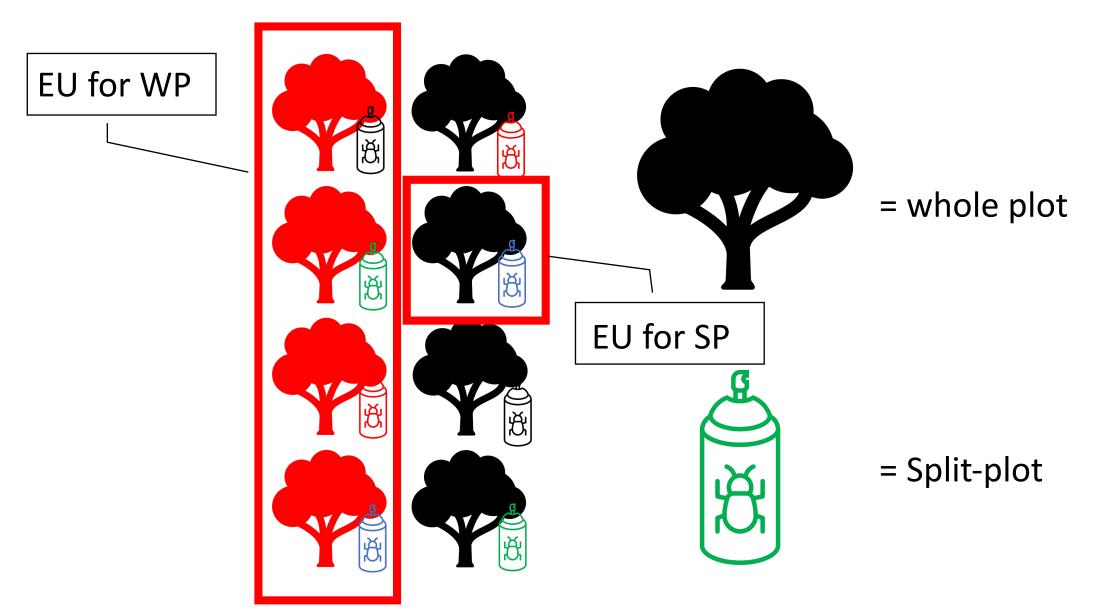

### But reality is often this.

#### But reality is often this.

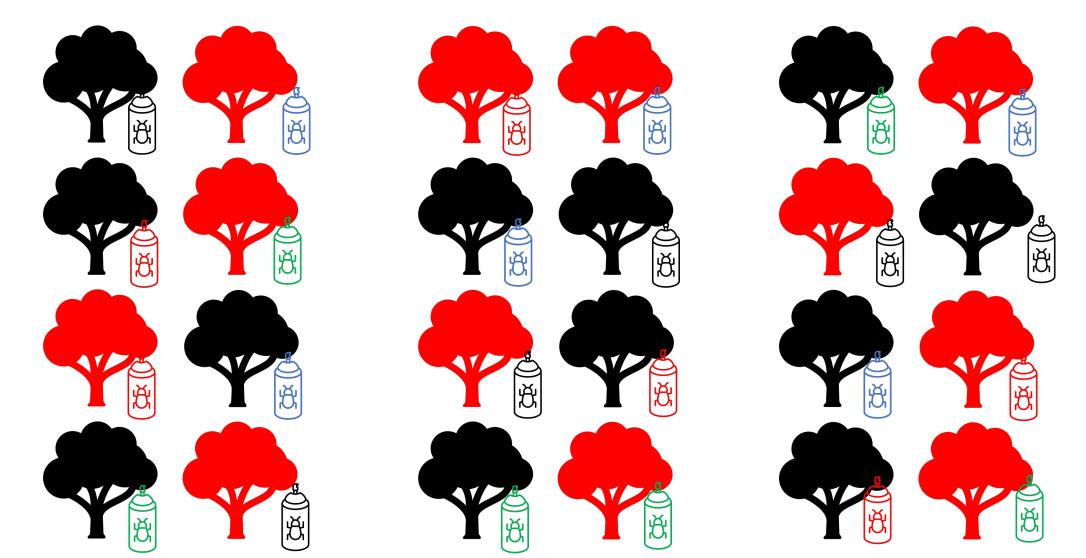

#### Split-plot design eases the implementation of trials.

#### RCBD vs. Split plot design

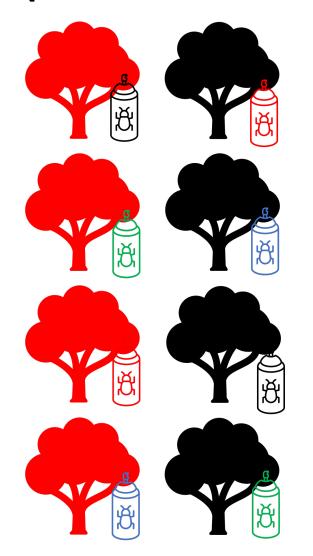

#### **RCBD**

 $Y = \mu$  + Chemicals + Cultivar + Chem.\*Cultiv. + Block + error

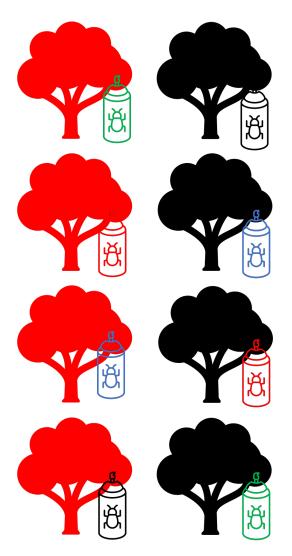

#### Split plot design

Y =  $\mu$  + Cultivars + WP error + Block + Chemical + Chem.\*Cultiv. + SP error

#### **RCBD**

Source of Variation	DF	Actual DF
Block (Rep)	b-1	3-1=2
Cultivar	c-1	2-1=1
Chemical	f-1	4-1=3
Cultivar x Chemical	(c-1)(f-1)	1*3 = 3
Error	(b-1)[(c-1)+(f-1)+(c-1)(f-1)]	2*(1+3+3) = 14
Total		23

Split plot design

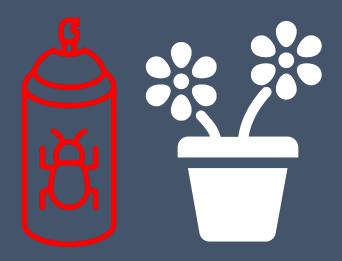

More difficult to find difference in the whole-plot.
Less affected in the Sub-plot.

Source of Variation	DF	
Block (Rep)	b-1	3-1=2
Cultivar	c-1	2-1=1
WP Error	(b-1)(c-1)	2*1 = 2
Chemical	f-1	4-1=3
Cultivar x Chemical	(c-1)(f-1)	1*3 = 3
SP Error	(b-1)[(f-1)+(c-1)(f-1)]	2*(3+3) = 12
Total		23

Designing is everything.

A wrong design can ruin any otherwise good experiments.

Let's spend more time to think about your experimental desgin before you start your trials.
